## Mathematics - Course 121

THE NORMAL DISTRIBUTION AND APPLICATIONS

## I THE NORMAL DISTRIBUTION

If a variable $x$ is normally distributed, then the probability that x lies within the interval ( $\mathrm{x}, \mathrm{x}+\mathrm{dx}$ ) is $\mathrm{P}_{\mathrm{x}} \mathrm{d}_{\mathrm{x}}$, where

$$
\frac{-(x-\mu)^{2}}{2 \sigma^{2}}
$$

$$
P_{x}=\frac{1}{\sqrt{2 \pi} \sigma} e
$$

where $\mu$ is the mean of the distribution - the expectation value of $x$, and
$\sigma$ is the standard deviation - the square root of the expectation value of $(x-\mu)^{2}$.

The Normal Distribution is shown in Figure l. Note that $P_{x} d_{x}$ is an incremental slice of the area under the curve reprepresenting $P_{x}$ as a function of $x$. Thus the probability that $x$ is less than ${ }^{\prime \prime} a^{\prime \prime}$,
$P(x<a)=\int_{-\infty}^{a} P_{x} d x$
ie, the sum of all incremental slices from $x=-\infty$ to $\mathbf{x}=\mathrm{a}$. Obviously, the total area under the curve,
$\int_{-\infty}^{\infty} P_{x} d x=1$,
since x must take some value.

II STANDARDIZED NORMAL DISTRIBUTION
The transformation
$z=\frac{x-\mu}{\sigma}$,
transforms the preceding expression for the Normal Distribution into the so called Standardized Normal Distribution

$$
1-\frac{z^{2}}{2}
$$

Figure 1
The Normal Distribution

Figure 1 shows corresponding values of $x$ and $z$ along the abscissa. The curve of Figure 1 can represent either $P_{x}$ vs $x$ or $P_{z}$ vs $z$, providing vertical and horizontal Normal Distribution has $z_{\text {a }}$ mean of zero and standard deviation of 1 .

The advantage of transferring to the Standardized Normal Distribution is that one and the same table of values of
$F(a) \equiv P(z<a)=\int_{-\infty}^{a} P_{z} d z$
can be used when working with any normally distributed variable. Table 1 is a table of $F(a)$ versus a.

## Notes re Use of Table 1

1. $F(a)$ is not tabulated for $a<0$ since, due to the symmetry of the distribution,

$$
F(-a)=1-F(a)
$$

2. $P(|z-a|>0)=2(1-F(a))$

3. $\quad P(-a<z<a)=2 F(a)-1$

4. a) $P(-1<z<1)=0.6827$
b) $P(-2<z<2)=0.9445$
c) $\quad P(-3<z<3)=0.9973$

## Example l

Suppose the distribution of the diameters of the ball bearings in a certain shipment is approximately normal with the mean $\mu=0.500 \mathrm{~cm}$ and the standard deviation $\sigma=0.010$ cm . If a ball bearing is effective when its diameter lies between 0.490 and 0.515 , find the probability of finding an effective ball bearing in this shipment.

## Solution

$$
\begin{aligned}
& P(0.490<x<0.515) \\
= & P\left(\frac{0.490-0.500}{0.010}<z<\frac{0.515-0.500}{0.010}\right) \\
= & P(-1.00<z<1.50) \\
= & F(1.50)-F(-1.00) \\
= & F(1.50)-(1-F(1.00)) \\
= & F(1.50)+F(1.00)-1 \\
= & 0.9332+0.8413-1 \\
= & 0.7745
\end{aligned}
$$

ie, approximately $77 \%$ of the ball bearings are effective, and this is the probability that any ball bearing selected at random will be effective.

## III FAILURE DISTRIBUTION FUNCTION

## DEFINITION

The failure distribution function (also called the failure density function) $f(t)$ of a component specifies the timedependent distribution of probability of failure over the operating life of the component, ie, $f(t) d t$ is the probability that the component will fail in the time interval (t,t+dt) - see Figure 2.

## Figure 2

Hypothetical Failure Distribution F'unction

With reference to Figure 2 , the probability $Q(T)$ that the component has failed by time $T$, ie, the component unreliability at time $T$, is given by the area under the $f(t)$ curve from $t=0$ to $t=T$,
ie, $Q(T)=\int_{0}^{T} f(t) d t$.
Similarly, the component reliability at time $T$ is given by

$$
R(T)=\int_{T}^{\infty} f(t) d t .
$$

## Example 2

The lifetime of a certain type of light bulb is normally distributed with mean 1000 hours and standard deviation 200 hours. If 2000 such bulbs are installed at time zero, calculate:
a) the expected number of bulb failures during the first 700 hours
b) the expected number of failures between 900 hours and 1300 hours
c) the time by which the first $10 \%$ of the bulbs have failed.

## Solution

a) $P(t<700)=P\left(z<\frac{700-1000}{200}\right)$

$$
=P(z<-1.5)
$$

$$
=F(-1.5)
$$

$$
=1-F(1.5)
$$

$$
=0.0668
$$

. Expected number of bulb failures in the interval $(0,700 \mathrm{~h})$

$$
\begin{aligned}
& =2000 \times 0.0668 \\
& =134
\end{aligned}
$$

b) $P(900 \leqslant t \leqslant 1300)=P\left(\frac{900-1000}{200} \leqslant z \leqslant \frac{1300-1000}{200}\right)$

$$
\begin{aligned}
& =P(-0.5 \leqslant z \leqslant 1.5) \\
& =F(1.5)-F(-0.5) \\
& =F(1.5)-(1-F(0.5)) \\
& =F(1.5)+F(0.5)-1 \\
& =0.9332+0.6915-1 \\
& =0.6247
\end{aligned}
$$

- Expected number of failures in the interval (900, 1300h)

$$
\begin{aligned}
& =2000 \times 0.6247 \\
& =1250
\end{aligned}
$$

c) $\quad F(a)=0.1 \Rightarrow 1-F(-a)=0.1$

$$
\text { ie, } \quad F(-a)=0.9
$$

$\therefore \quad-\mathrm{a}=1.28$ (from Table 1$)$
ie, $\frac{T-1000}{200}=-1.28$
ie, $\quad T=744$

- first lot bulbs expected to fail during the interval (0,744h).

## ASS IGNMENT

1. Specifications for a certain job call for washers with an inside diameter of $0.250 \pm 0.005$ inches. If the inside diameter of the washers made by a given manufacturer are normally distributed with $\mu=0.251$ and $\sigma=$ 0.003 , what percentage of these washers will meet specifications?
2. A study showed that the lifetimes of a certain kind of automobile battery are normally distributed with a mean of 1248 days and a standard deviation of 185 days. If the manufacturer wishes to guarantee the battery for 36 months (a month is taken to be 30 days), what percentage of the batteries will have to be replaced under the guarantee?
L. Haacke
